

Exercise 1 (Progress Property)

Let t be a closed and well-typed term, i.e. $[] \vdash t : \tau$ for some τ . Show that t is either a value or there is a t' such that $t \rightarrow_{cbv} t'$.

Solution

The proof follows an induction on the derivation of $[] \vdash t : \tau$. The variable case cannot occur. Abstractions are values, so there is nothing to do here. For the application case, assume $t = t_1 t_2$ and $[] \vdash t_1 : \tau_1 \rightarrow \tau_2$ and $[] \vdash t_2 : \tau_1$. By the induction hypothesis, both, t_1 and t_2 , can take a step or are a value. If t_1 can take a step, we can use the left application rule on t . If t_1 is a value and t_2 can take a step, then the right application rule can be used. If t_1 and t_2 are both values, we know $t_1 = \lambda x. t'_1$ for some t'_1 as t_1 is of type $\tau_1 \rightarrow \tau_2$. Thus we can apply the rule for reducing an abstraction.

Exercise 2 (Normal Form)

Show that every type-correct λ^{\rightarrow} -term has a β -normal form.

Solution

We prove the statement by coming up with a terminating reduction relation \rightarrow_p that, when repeatedly applied, reduces a given term to β -normal form. Furthermore, we define a well-founded order $<_T$ on terms and show that $t_1 \rightarrow_p t_2$ implies $t_1 <_T t_2$. By induction on $<_T$ it then follows that \rightarrow_p is terminating.

The reduction strategy is chosen such that it decreases the types of subterms.

Let $|\tau|$ be the size of a type τ , i.e. the number of function-arrows occurring in τ .

$$\begin{aligned} |\alpha| &= 0 \\ |\alpha \rightarrow \beta| &= |\alpha| + |\beta| + 1 \end{aligned}$$

With this measure, we can assign a natural number to each β -redex:

$$|(\lambda x. s) t|^\Gamma = |\tau_1 \rightarrow \tau_2| \quad \text{where} \quad \Gamma \vdash (\lambda x. s) : \tau_1 \rightarrow \tau_2$$

We assign each term t a multiset M_t . In order to account for the potentially non-empty environment Γ in the subterms of t , we first define M_t^Γ recursively and then set $M_t := M_t^{[]}$.

$$\begin{aligned} t = u v &\implies M_t^\Gamma = M_u^\Gamma \cup M_v^\Gamma \cup \{|u v|^\Gamma. u v \text{ is a } \beta\text{-redex}\} \\ t = (\lambda x. s) &\implies \Gamma \vdash (\lambda x. s) : \tau_1 \rightarrow \tau_2 \implies M_t^\Gamma = M_s^{\Gamma[x:\tau_1]} \\ t = x &\implies M_t = \{\} \end{aligned}$$

We can view multisets as functions into the natural numbers and define an ordering on them:

$$M <_M N \iff M \neq N \wedge (\forall y. M(y) > N(y) \implies (\exists x. y < x \wedge M(x) < N(x)))$$

It can be proved that the multiset ordering terminates (is well-founded). The ordering naturally extends to terms, i.e. $u <_T v \iff M_u <_M M_v$.

If one regards a β -redex of the form $r = (\lambda x. u) v$ with $\Gamma \vdash r : \tau$ and u and v in β -NF, then we have $M_r >_M M_{r'}$ for the reduct $r' = u[v/x]$.

This is because although the substitution may create new β -redexes w , we have $|w| < |r|$ for all those w in r' :

Note that $\Gamma \vdash (\lambda x. u) : \tau_1 \rightarrow \tau_2$ and $\Gamma \vdash v : \tau_2$ for some τ_1, τ_2 must hold. Since $v \in \mathbf{NF}$, w is of the form $(v v')$ with $v = (\lambda x. s)$ for some s and thus $|w| = |\tau_1| < |\tau_1 \rightarrow \tau_2| = |r|$.

Thus, if we choose a reduction strategy \rightarrow_p that reduces an innermost β -redex in t , we have:

$$t \rightarrow_p t' \implies M_t >_M M_{t'}$$

We can obtain such a reduction strategy by restricting the first rule of \rightarrow_β to:

$$\frac{s \in \mathbf{NF} \quad t \in \mathbf{NF}}{(\lambda x. s) t \rightarrow_p s[t/x]}$$

As the multiset ordering terminates, also the chosen reduction strategy must terminate. If it terminates with t' , then t' is in β -NF because otherwise t' would contain a regex and therefore an innermost regex that can be reduces with \rightarrow_p .

□

Homework 3 (Typing)

a) Prove:

$$\boxed{} \vdash (\lambda x: \tau_2 \rightarrow \tau_3. \lambda y: \tau_1 \rightarrow \tau_2. \lambda z: \tau_1. x (y z)) : (\tau_2 \rightarrow \tau_3) \rightarrow (\tau_1 \rightarrow \tau_2) \rightarrow \tau_1 \rightarrow \tau_3$$

b) Give suitable solutions for $?\tau_1$, $?\tau_2$, $?\tau_3$ and $?\tau_4$ and prove that the term is type-correct given your solution.

$$\boxed{} \vdash \lambda x:?\tau_1. \lambda y:?\tau_2. \lambda z:?\tau_3. x y (y z) :?\tau_4$$

Homework 4 (β -reduction preserves types)

A type system has the *subject reduction property* if evaluating an expression preserves its type. Prove that the simply typed λ -calculus (λ^{\rightarrow}) has the subject reduction property:

$$\Gamma \vdash t: \tau \wedge t \rightarrow_{\beta} t' \implies \Gamma \vdash t': \tau$$

Hints: Use induction over the inductive definition of \rightarrow_{β} (Def. 1.2.2). State your inductive hypotheses precisely – it may help to introduce a binary predicate $P(t, t')$ to express the property you are proving by induction. Also note that the proof will require *rule inversion*: Given $\Gamma \vdash t: \tau$, the shape of t (variable, application, or λ -abstraction) may determine which typing rule must have been used to derive the typing judgment.

Within your proof, you are free to use the following lemma about substitution:

$$\Gamma \vdash u: \tau_0 \wedge \Gamma[x: \tau_0] \vdash t: \tau \implies \Gamma \vdash t[u/x]: \tau \tag{1}$$

Homework 5 (Implementation of multiset-ordering and reduction)

Implement the multiset ordering and the reduction strategy from the second tutorial exercise in your favorite programming language.
